

WU #17 - Outliers 2

Math 158 - Jo Hardin

Thursday 3/31/2022

Name: _____

Names of people you worked with: _____

Consider data taken on 301 fast food items with `calories` modeled on `sodium`, `total_carbs`, and `total_fat`. Below are some of the metrics discussed in class to assess the influence of particular points on the model. (See class notes for R code to calculate the metrics.) The second table reports columns of `dfbetas()`.

What would you do with the observations?

```
fastfood <- fastfood %>% drop_na()
ff_lm <- lm(calories ~ sodium + total_carb + total_fat, data=fastfood)
```

```

```

Solution:

None of the observations are hugely influential. The most outlying of the observations impacts the beta values and their own predictions both just a bit. They don't seem to impact the other predictions much.

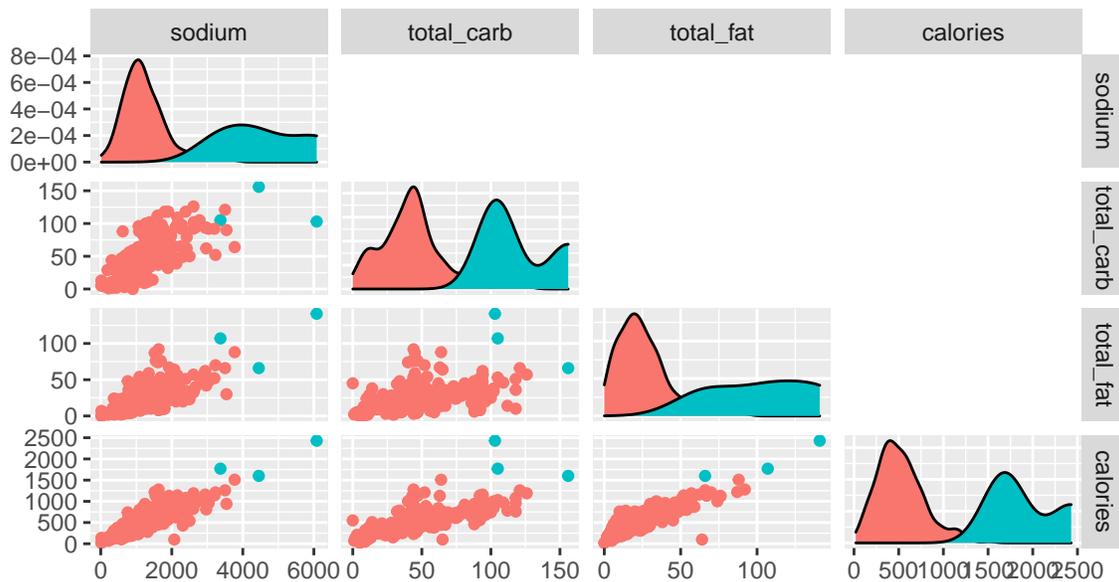

I'd be hesitant to take out the variables without a good external reason. Although, in looking at the dataset, I might subset the variables to be only those which can be thought of as one meal for one person (i.e., not 40 Piece Chicken McNuggets). But that decision would certainly be very subjective!

Outliers are:

20 piece Buttermilk Crispy Chicken Tenders

10 piece Sweet N' Spicy Honey BBQ Glazed Tenders

40 piece Chicken McNuggets

Note that if other variables are added into the model, the particular observations become less influential.

```
ff2_lm <- lm(calories ~ sodium + total_carb + total_fat +  
             protein + cholesterol + protein, data=fastfood)
```
